

## Remarks

### **1. Summary of Office Action**

In the Office Action mailed August 19, 2008, the Examiner rejected claims 1-7, 12-13, 15, and 17 under 35 U.S.C. § 103(a) as being allegedly obvious over U.S. Patent Application Pub. No. 2002/0151302 (Schmidt) in view of the article, "IP Centrex Creates New Opportunities for Equipment Manufacturers" (Stamp) and U.S. Patent No. 4,802,199 (Lange). Further, the Examiner rejected claims 8 and 18 under 35 U.S.C. § 103(a) as being allegedly obvious over Schmidt, Stamp and Lange in view of U.S. Patent Application Pub. No. 2002/0120759 (Faccin). Yet further, the Examiner rejected claims 9, 11, and 20 under 35 U.S.C. § 103(a) as being allegedly obvious over Schmidt, Stamp and Lange in view of U.S. Patent No. 5,912,963 (Begeja). Additionally, the Examiner rejected claim 14 under 35 U.S.C. § 103(a) as being allegedly obvious over Schmidt, Stamp and Lange in view of U.S. Patent Application Pub. No. 2002/0193107 (Nascimento, Jr.). Moreover, the Examiner rejected claim 16 under 35 U.S.C. § 103(a) as being allegedly obvious over Schmidt, Stamp and Lange in view of U.S. Patent No. 6,757,269 (Dorenbosch).

### **2. Status of the Claims**

Currently pending are claims 1-9, 11-18, and 20, of which claims 1 and 12 are independent and the remainder are dependent.

### **3. Response to Rejections**

The Examiner has rejected the subject matter of independent claims 1 and 12 under 35 U.S.C. § 103(a) as being allegedly obvious over Schmidt in view of Stamp and Lange. However, the presently claimed subject matter does not reasonably or logically follow from the combination of Schmidt, Stamp, and Lange.

Claims 1 and 12 are directed to the wireless wide area network (WWAN) backup of an enterprise IP telephony system. The enterprise IP telephony system is configured to allow a call server that facilitates signaling to be located outside of the enterprise network, for example, on a packet-switched network that has a wireline link to the enterprise network. According to this configuration, calls between telephone stations that are all on the enterprise network will have bearer paths within the enterprise network between the enterprise telephone stations, and signaling traffic will traverse both the enterprise network and the packet switched network. However, for calls between a telephone station on the enterprise network and one or more telephone stations that are outside of the enterprise network, bearer paths are not limited to being within the enterprise network.

The enterprise network is also connected to the packet switched network via a WWAN backup link. If the wireline link between the enterprise network and the packet switched network fails, the WWAN backup link is initiated. Due to the potentially limited capacity of the WWAN link, it may be advantageous for the call server to restrict the establishment of some types of calls while the WWAN link is in use. While calls between telephone stations that are all on the enterprise network will only require WWAN capacity for signaling traffic, calls between a telephone station on the enterprise network and one or more telephone stations that are outside of the enterprise network will require WWAN capacity for both signaling and bearer traffic.

Thus, in response to detecting the failure of the wireline link, calls between telephone stations that are all on the enterprise network are permitted because these calls use relatively little WWAN capacity. But calls between a telephone station on the enterprise network and one or more telephone stations outside of enterprise network use significantly more WWAN capacity. Therefore, in response to the failure of the wireline link, the latter type of call may be

restricted. However, not all calls between a telephone station on the enterprise network and one or more telephone stations that are outside of the enterprise network should be restricted. Accordingly, the bearer path of high-priority calls, such as emergency calls, may use the WWAN link.

The Schmidt reference teaches an enterprise network that supports telephony, where the enterprise network has both a wireline link and a wireless link to an external network. Schmidt also teaches switching from routing calls via the wireline link to routing calls via the wireless link when connectivity on the wireline link is lost. The Examiner conceded that Schmidt does not teach a call server on the external packet switched network, where the call server engages in packet switched signaling to set up calls between the enterprise telephone stations. However, with respect to the presently pending claims, Schmidt is even more deficient.

Schmidt also does not teach allowing, upon loss of the wireline link and through use of the external call server, continued setup of calls inside the enterprise network between the enterprise telephone stations, wherein bearer paths are within the enterprise network. Furthermore, Schmidt does not teach call-server-logic at the call server, responsive to the loss of the wireline link, restricting outside calling between a telephone station on the enterprise network and a telephone station not on the enterprise network via the WWAN connection, wherein restricted calls are not permitted to connect.

The Stamp reference teaches a call server (Network Gateway) on the external packet switched network that engages in packet switched signaling to set up calls. However, Stamp does not teach the call server setting up calls between the enterprise telephone stations. More importantly, Stamp does not disclose the call server allowing setup of calls inside the enterprise network between the enterprise telephone stations, *wherein bearer paths are within the*

*enterprise network*. At page 3, paragraph C, Stamp specifically teaches sending packetized voice and IP telephony messages over the LAN and the broadband access facility, to the call server. Thus, Stamp requires transmitting bearer traffic to the call server, which is inapposite to claims 1 and 12.

In the Final Office Action mailed August 19, 2008, the Examiner conceded that the combination of Schmidt and Stamp does not teach an external call server allowing setup of calls inside the enterprise network between the enterprise telephone stations, where the bearer paths are within the enterprise network, while preventing setup of all but certain designated calls having bearer paths extending from the enterprise network and through the WWAN connection. However, in the Advisory action mailed November 5, 2008, the Examiner contended that Stamp teaches the element of claim 1 that recites, “at the call server, allowing setup of calls having bearer paths within the enterprise network between the enterprise telephone stations...”

Stamp does not teach a signaling path reaching from the enterprise network to the call server, *while the bearer paths remain within the enterprise network between the telephone stations*. Furthermore, in claims 1 and 12 as currently amended, this element is in response to detecting the loss of the wireline link. But Stamp does not teach a call server taking action in response to loss of a wireline link. Thus, the Examiner has failed to establish that Stamp teaches this element.

In the Final Office Action mailed August 19, 2008, the Examiner attempted to overcome the deficiencies in Schmidt and Stamp with Lange. However, Lange falls short. The Lange reference teaches a circuit-switched telephony system. Lange’s system connects two enterprise private branch exchange (PBX) telephony systems (system 110 and system 130 of Lange’s Figure 1), each at different physical locations, to a public-switched telephone network (PSTN).

The problem that Lange attempts to address is how to efficiently allow a remote office PBX (system 110) to interconnect to a headquarters PBX (system 130) such that both sites share uniform dialing features. Lange relies on the concept of providing “virtual facilities” in the form of hypothetical telephony trunks that mimic private telephony trunks between the PBX systems, but actually pass through an interim switch. With reference to Lange’s Figure 1, Lange describes a virtual facility 101. Virtual facility 101 routes traffic between system 110 and system 130 via tie-lines 104 and central office / PBX 140.

Lange does not teach the system architecture that is recited in claims 1 and 12. Claims 1 and 12 are directed to an external call server allowing calls between telephone stations within a single enterprise network when wireline access to the external call server is unavailable. The system architecture taught by Lange contains an external call server (e.g., central office / PBX 140), but also internal call servers (the PBX’s labeled system 110 and system 130). However, neither of these two distinct types of call servers constitute the subject matter of claims 1 and 12.

In the Advisory Action mailed November 5, 2008, it appears that the Examiner contended that the central office / PBX of Lange is analogous to the call server in the present invention. However, unlike claims 1 and 12, Lange does not teach packet-based signaling traffic between an external call server and an enterprise network, wherein this packet-based signaling is used, in response to loss of a wireline link to the enterprise network, to set up calls having bearer paths that remain within the enterprise network while restricting some calls having bearer paths that leave the enterprise network.

Thus, Lange does not make up for the deficiencies of Schmidt and Stamp. The combination of Schmidt, Stamp and Lange does not teach or logically lead to an external call server allowing setup of calls inside an enterprise network between enterprise telephone stations,

where the bearer paths are within the enterprise network. These references also do not teach or logically lead to an external call server, in response to loss of a wireline link to the enterprise network, restricting outside calling between a telephone station on the enterprise network and a telephone station not on the enterprise network via a WWAN connection, wherein restricted calls are not permitted to connect.

Given the deficiencies of Schmidt, Stamp, and Lange, and given that the currently pending claimed subject matter does not reasonably or logically follow from the combination of these references, the Examiner has not established *prima facie* obviousness of claims 1 and 12. Therefore, Applicants submit that claims 1 and 12 are allowable. Furthermore, and without conceding any assertions made by the Examiner that are not addressed herein, Applicants submit that claims 2-9, 11, 13-18, and 20 are allowable for at least the reason that they depend from an allowable claim.

#### **4. Conclusion**

In view of the foregoing, Applicants respectfully request favorable reconsideration and allowance of the claims. Should the Examiner wish to discuss this case with the undersigned, the Examiner is invited to call the undersigned at (312) 913-3361.

Respectfully submitted,

**McDONNELL BOEHNEN  
HULBERT & BERGHOFF LLP**
